Julia is a scientific programming language that is free and open source.\textsuperscript{1} It is a relatively new language that borrows inspiration from languages like Python, MATLAB, and R. It was selected for use in this book because it is sufficiently high level\textsuperscript{2} so that the algorithms can be compactly expressed and readable while also being fast. This book is compatible with Julia version 1.6. This appendix introduces the concepts necessary for understanding the included code, omitting many of the advanced features of the language.

\section*{G.1 Types}

Julia has a variety of basic types that can represent data given as truth values, numbers, strings, arrays, tuples, and dictionaries. Users can also define their own types. This section explains how to use some of the basic types and how to define new types.

\subsection*{G.1.1 Booleans}

The \textit{Boolean} type in Julia, written \texttt{Bool}, includes the values \texttt{true} and \texttt{false}. We can assign these values to variables. Variable names can be any string of characters, including Unicode, with a few restrictions.

\begin{verbatim}
   \alpha = true
done = false
\end{verbatim}

The variable name appears on the left-hand side of the equal sign; the value that variable is to be assigned is on the right-hand side.

\footnote{Julia may be obtained from \url{http://julialang.org}.}

\footnote{In contrast with languages like C++, Julia does not require programmers to worry about memory management and other lower-level details, yet it allows low-level control when needed.}
We can make assignments in the Julia console. The console, or REPL (for read, eval, print, loop), will return a response to the expression being evaluated. The # symbol indicates that the rest of the line is a comment.

```
julia> x = true
true
julia> y = false; # semicolon suppresses the console output
julia> typeof(x)
Bool
julia> x == y # test for equality
false
```

The standard Boolean operators are supported.

```
julia> !x      # not
false
julia> x && y # and
false
julia> x || y # or
true
```

### G.1.2 Numbers

Julia supports integer and floating point numbers as shown here:

```
julia> typeof(42)
Int64
julia> typeof(42.0)
Float64
```

Here, Int64 denotes a 64-bit integer, and Float64 denotes a 64-bit floating point value. We can perform the standard mathematical operations:

```
julia> x = 4
4
julia> y = 2
2
julia> x + y
6
julia> x - y
2
julia> x * y
8
julia> x / y
2.0
```

---

© 2022 Massachusetts Institute of Technology, shared under a under a Creative Commons CC-BY-NC-ND license.

2021-07-20 17:04:22-07:00, revision 2babf1f, comments to bugs@algorithmsbook.com
Note that the result of `x / y` is a `Float64`, even when `x` and `y` are integers. We can also perform these operations at the same time as an assignment. For example, `x += 1` is shorthand for `x = x + 1`.

We can also make comparisons:

```julia
julia> 3 > 4
false
julia> 3 >= 4
false
julia> 3 ≥ 4  # unicode also works, use \ge[tab] in console
false
julia> 3 < 4
true
julia> 3 <= 4
true
julia> 3 ≤ 4  # unicode also works, use \le[tab] in console
true
julia> 3 == 4
false
julia> 3 < 4 < 5
true
```

## G.1.3 Strings

A *string* is an array of characters. Strings are not used very much in this textbook except for reporting certain errors. An object of type `String` can be constructed using " characters. For example:

```julia
julia> x = "optimal"
"optimal"
julia> typeof(x)
String
```
G.1.4 Symbols

A symbol represents an identifier. It can be written using the : operator or constructed from strings.

```julia
julia> :A
:A
julia> :Battery
:Battery
julia> Symbol("Failure")
:Failure
```

G.1.5 Vectors

A vector is a one-dimensional array that stores a sequence of values. We can construct a vector using square brackets, separating elements by commas.

```julia
julia> x = [];
    # empty vector
julia> x = trues(3);
    # Boolean vector containing three trues
julia> x = ones(3);
    # vector of three ones
julia> x = zeros(3);
    # vector of three zeros
julia> x = rand(3);
    # vector of three random numbers between 0 and 1
julia> x = [3, 1, 4];
    # vector of integers
julia> x = [3.1415, 1.618, 2.7182];
    # vector of floats
```

An array comprehension can be used to create vectors.

```julia
julia> [sin(x) for x in 1:5]
5-element Vector{Float64}:
  0.8414709848078965
  0.9092974268256817
  0.1411200080598672
 -0.7568024953079282
 -0.9589242746631385
```

We can inspect the type of a vector:

```julia
julia> typeof([3, 1, 4])
# 1-dimensional array of Int64s
Vector{Int64} (alias for Array{Int64, 1})
```

We index into vectors using square brackets.
We can pull out a range of elements from an array. Ranges are specified using a colon notation.

```julia
julia> x = [1, 2, 5, 3, 1]
5-element Vector{Int64}:
  1
  2
  5
  3
  1
julia> x[1:3] # pull out the first three elements
3-element Vector{Int64}:
  1
  2
  5
julia> x[1:2:end] # pull out every other element
3-element Vector{Int64}:
  1
  5
  1
julia> x[end:-1:1] # pull out all the elements in reverse order
5-element Vector{Int64}:
  1
  3
  5
  2
  1
```

We can perform a variety of different operations on arrays. The exclamation mark at the end of function names is used to indicate that the function `mutates` (i.e., changes) the input.

```julia
julia> length(x)
5
julia> [x, x] # concatenation
2-element Vector{Vector{Int64}}:
```

© 2022 Massachusetts Institute of Technology, shared under a under a Creative Commons CC-BY-NC-ND license. 2021-07-20 17:04:22-07:00, revision 2babf1f, comments to bugs@algorithmsbook.com
[1, 2, 5, 3, 1]
[1, 2, 5, 3, 1]

```julia
julia> push!(x, -1)  # add an element to the end
6-element Vector{Int64}:
  1
  2
  5
  3
  1
-1
```

```julia
julia> pop!(x)        # remove an element from the end
-1
```

```julia
julia> append!(x, [2, 3])  # append [2, 3] to the end of x
7-element Vector{Int64}:
  1
  2
  5
  3
  1
  2
  3
```

```julia
julia> sort!(x)       # sort the elements, altering the same vector
7-element Vector{Int64}:
  1
  1
  2
  2
  3
  3
  5
```

```julia
julia> sort(x);      # sort the elements as a new vector
```

```julia
julia> x[1] = 2; print(x)  # change the first element to 2
[2, 1, 2, 2, 3, 3, 5]
```

```julia
julia> x = [1, 2];
julia> y = [3, 4];
julia> x + y           # add vectors
2-element Vector{Int64}:
  4
  6
```

```julia
julia> 3x - [1, 2]     # multiply by a scalar and subtract
2-element Vector{Int64}:
  2
  4
```

```julia
julia> using LinearAlgebra
```

© 2022 Massachusetts Institute of Technology, shared under a Creative Commons CC-BY-NC-ND license.
It is often useful to apply various functions elementwise to vectors. This is a form of broadcasting. With infix operators (e.g., `+`, `*`, and `^`), a dot is prefixed to indicate elementwise broadcasting. With functions like `sqrt` and `sin`, the dot is postfixied.

```julia
julia> x .* y  # elementwise multiplication
2-element Vector{Int64}:
  3
  8
julia> x .^ 2  # elementwise squaring
2-element Vector{Int64}:
  1
  4
julia> sin.(x)  # elementwise application of sin
2-element Vector{Float64}:
  0.8414709848078965
  0.9092974268256817
julia> sqrt.(x)  # elementwise application of sqrt
2-element Vector{Float64}:
  1.0
  1.4142135623730951
```

### G.1.6 Matrices

A *matrix* is a two-dimensional array. Like a vector, it is constructed using square brackets. We use spaces to delimit elements in the same row and semicolons to delimit rows. We can also index into the matrix and output submatrices using ranges.

```julia
julia> X = [1 2 3; 4 5 6; 7 8 9; 10 11 12];
julia> typeof(X)  # a 2-dimensional array of Int64s
Matrix{Int64} (alias for Array{Int64, 2})
julia> X[2]  # second element using column-major ordering
4
julia> X[3,2]  # element in third row and second column
8
```
### Appendix G. Julia

```julia
julia> X[1,:]
# extract the first row
3-element Vector{Int64}:
1
2
3
```

```julia
julia> X[:,2]
# extract the second column
4-element Vector{Int64}:
2
5
8
11
```

```julia
julia> X[:,1:2]
# extract the first two columns
4×2 Matrix{Int64}:
1 2
4 5
7 8
10 11
```

```julia
julia> X[1:2,1:2]
# extract a 2x2 submatrix from the top left of x
2x2 Matrix{Int64}:
1 2
4 5
```

```julia
julia> Matrix{Float64}
# alias for a 2-dimensional array
Matrix{Float64} (alias for Array{Float64, 2})
```

We can also construct a variety of special matrices and use array comprehensions:

```julia
julia> Matrix(1.0I, 3, 3)
# 3x3 identity matrix
3×3 Matrix{Float64}:
1.0 0.0 0.0
0.0 1.0 0.0
0.0 0.0 1.0
```

```julia
julia> Matrix(Diagonal([3, 2, 1]))
# 3x3 diagonal matrix with 3, 2, 1 on diagonal
3×3 Matrix{Int64}:
3 0 0
0 2 0
0 0 1
```

```julia
julia> zeros(3,2)
# 3x2 matrix of zeros
3×2 Matrix{Float64}:
0.0 0.0
0.0 0.0
0.0 0.0
```

```julia
julia> rand(3,2)
# 3x2 random matrix
3×2 Matrix{Float64}:
0.383507 0.84191
```

© 2022 Massachusetts Institute of Technology, shared under a Creative Commons CC-BY-NC-ND license.
Matrix operations include the following:

```julia
julia> X'         # complex conjugate transpose
3×4 adjoint(::Matrix{Int64}) with eltype Int64:
   1  4  7  10
   2  5  8  11
   3  6  9  12

julia> 3X .+ 2   # multiplying by scalar and adding scalar
4×3 Matrix{Int64}:
   5  8  11
  14 17 20
  23 26 29
  32 35 38

julia> X = [1 3; 3 1]; # create an invertible matrix
julia> inv(X)       # inversion
2×2 Matrix{Float64}:
  -0.125  0.375
  0.375 -0.125

julia> det(X)      # determinant (requires LinearAlgebra)
-8.0

julia> [X X]       # horizontal concatenation, same as hcat(X, X)
2×4 Matrix{Int64}:
   1  3  1  3
   3  1  3  1

julia> [X; X]      # vertical concatenation, same as vcat(X, X)
4×2 Matrix{Int64}:
   1  3
   3  1
   1  3
   3  1

julia> sin.(X)     # elementwise application of sin
2×2 Matrix{Float64}:
  0.841471  0.14112
  0.14112  0.841471

julia> map(sin, X) # elementwise application of sin
2×2 Matrix{Float64}:
  0.841471  0.14112
```
G.1.7 Tuples

A *tuple* is an ordered list of values, potentially of different types. They are constructed with parentheses. They are similar to vectors, but they cannot be mutated.

```
julia> x = ()  # the empty tuple
()
julia> isempty(x)
true
julia> x = (1,)  # tuples of one element need the trailing comma
(1,)
julia> typeof(x)
Tuple{Int64}
julia> x = (1, 0, [1, 2], 2.5029, 4.6692)  # third element is a vector
(1, 0, [1, 2], 2.5029, 4.6692)
julia> typeof(x)
Tuple{Int64, Int64, Vector{Int64}, Float64, Float64}
```

```
julia> x[2]
0
julia> x[end]
4.6692
julia> x[4:end]
(2.5029, 4.6692)
julia> length(x)
5
julia> x = (1, 2)
(1, 2)
julia> a, b = x;
julia> a
1
julia> b
2
```

G.1.8 Named Tuples

A *named tuple* is like a tuple but where each entry has its own name.
```julia
julia> x = (a=1, b=-Inf)
(a = 1, b = -Inf)
julia> x isa NamedTuple
true
julia> x.a
1
julia> a, b = x;
```

```
julia> a
1
julia> (; a=>10)
(a = 10,)
julia> (; a=>10, b=>11)
(a = 10, b = 11)
julia> merge(x, (d=3, e=10))  # merge two named tuples
(a = 1, b = -Inf, d = 3, e = 10)
```

### G.1.9 Dictionaries

A dictionary is a collection of key-value pairs. Key-value pairs are indicated with a double arrow operator =>. We can index into a dictionary using square brackets just as with arrays and tuples.

```julia
julia> x = Dict();  # empty dictionary
julia> x[3] = 4  # associate key 3 with value 4
4
julia> x = Dict(3=>4, 5=>1)  # create a dictionary with two key-value pairs
Dict{Int64, Int64} with 2 entries:
  5 => 1
  3 => 4
julia> x[5]  # return the value associated with key 5
1
julia> haskey(x, 3)  # check whether dictionary has key 3
true
julia> haskey(x, 4)  # check whether dictionary has key 4
false
```

### G.1.10 Composite Types

A composite type is a collection of named fields. By default, an instance of a composite type is immutable (i.e., it cannot change). We use the `struct` keyword and then give the new type a name and list the names of the fields.

```julia
```
struct A
    a
    b
end

Adding the keyword `mutable` makes it so that an instance can change.

mutable struct B
    a
    b
end

Composite types are constructed using parentheses, between which we pass in values for each field. For example,

\[ x = A(1.414, 1.732) \]

The double-colon operator can be used to specify the type for any field.

struct A
    a::Int64
    b::Float64
end

These type annotations require that we pass in an `Int64` for the first field and a `Float64` for the second field. For compactness, this text does not use type annotations, but it is at the expense of performance. Type annotations allow Julia to improve runtime performance because the compiler can optimize the underlying code for specific types.

G.1.11 Abstract Types

So far we have discussed concrete types, which are types that we can construct. However, concrete types are only part of the type hierarchy. There are also abstract types, which are supertypes of concrete types and other abstract types.

We can explore the type hierarchy of the `Float64` type shown in figure G.1 using the `supertype` and `subtypes` functions.

© 2022 Massachusetts Institute of Technology, shared under a Creative Commons CC-BY-NC-ND license.
2021-07-20 17:04:22-07:00, revision 2babf1f, comments to bugs@algorithmsbook.com
julia> supertype(Float64)
AbstractFloat
julia> supertype(AbstractFloat)
Real
julia> supertype(Real)
Number
julia> supertype(Number)
Any
julia> supertype(Any)  # Any is at the top of the hierarchy
Any
julia> using InteractiveUtils  # required for using subtypes in scripts
julia> subtypes(AbstractFloat)  # different types of AbstractFloats
4-element Vector{Any}:
  BigFloat
  Float16
  Float32
  Float64
julia> subtypes(Float64)  # Float64 does not have any subtypes
Type[]

We can define our own abstract types.

abstract type C end
abstract type D <: C end  # D is an abstract subtype of C
struct E <: D  # E is a composite type that is a subtype of D
  a
end

G.1.12  Parametric Types

Julia supports parametric types, which are types that take parameters. The parameters to a parametric type are given within braces and delimited by commas. We have already seen a parametric type with our dictionary example.

julia> x = Dict(3↦1.4, 1↦5.9)
Dict{Int64, Float64} with 2 entries:
  3 ⇒ 1.4
  1 ⇒ 5.9

For dictionaries, the first parameter specifies the key type, and the second parameter specifies the value type. The example has Int64 keys and Float64 values, making the dictionary of type Dict{Int64, Float64}. Julia was able to infer these types based on the input, but we could have specified it explicitly.
While it is possible to define our own parametric types, we do not need to do so in this text.

\[ x = \text{Dict} \{ \text{Int64}, \text{Float64} \}(3 \mapsto 1.4, 1 \mapsto 5.9); \]

G.2 Functions

A function maps its arguments, given as a tuple, to a result that is returned.

G.2.1 Named Functions

One way to define a named function is to use the function keyword, followed by the name of the function and a tuple of names of arguments.

```julia
function f(x, y)
    return x + y
end
```

We can also define functions compactly using assignment form.

```julia
f(x, y) = x + y;
f(3, 0.1415)
```

G.2.2 Anonymous Functions

An anonymous function is not given a name, though it can be assigned to a named variable. One way to define an anonymous function is to use the arrow operator.

```julia
h = x -> x^2 + 1 # assign anonymous function with input x to a variable h
#1 (generic function with 1 method)
h(3)
```

```julia
g(f, a, b) = [f(a), f(b)]; # applies function f to a and b and returns array
g(h, 5, 10)
2-element Vector{Int64}:
  26
  101
```

```
```
G.2.3 Callable Objects

We can define a type and associate functions with it, allowing objects of that type to be *callable*.

```julia
julia> (x::A)() = x.a + x.b # adding a zero-argument function to the type A defined earlier
julia> (x::A)(y) = y*x.a + x.b # adding a single-argument function
julia> x = A(22, 8);
julia> x()
30
julia> x(2)
52
```

G.2.4 Optional Arguments

We can assign a default value to an argument, making the specification of that argument optional.

```julia
julia> f(x=10) = x^2;
julia> f()
100
julia> f(3)
9
julia> f(x, y, z=1) = x*y + z;
julia> f(1, 2, 3)
5
julia> f(1, 2)
3
```

G.2.5 Keyword Arguments

Functions may use keyword arguments, which are arguments that are named when the function is called. Keyword arguments are given after all the positional arguments. A semicolon is placed before any keywords, separating them from the other arguments.

```julia
julia> f(; x = 0) = x + 1;
julia> f()
1
julia> f(x = 10)
11
julia> f(x, y = 10; z = 2) = (x + y)*z;
julia> f(1)
```

© 2022 Massachusetts Institute of Technology, shared under a under a Creative Commons CC-BY-NC-ND license.
2021-07-20 17:04:22-07:00, revision 2babf1f, comments to bugs@algorithmsbook.com
G.2.6 Dispatch

The types of the arguments passed to a function can be specified using the double colon operator. If multiple methods of the same function are provided, Julia will execute the appropriate method. The mechanism for choosing which method to execute is called dispatch.

```
 julia> f(x::Int64) = x + 10;
 julia> f(x::Float64) = x + 3.1415;
 julia> f(1)
 11
 julia> f(1.0)
 4.141500000000001
 julia> f(1.3)
 4.4415000000000004
```

The method with a type signature that best matches the types of the arguments given will be used.

```
 julia> f(x) = 5;
 julia> f(x::Float64) = 3.1415;
 julia> f([3, 2, 1])
 5
 julia> f(0.00787499699)
 3.1415
```

G.2.7 Splatting

It is often useful to *splat* the elements of a vector or a tuple into the arguments to a function using the ... operator.
G.3 Control Flow

We can control the flow of our programs using conditional evaluation and loops. This section provides some of the syntax used in the book.

G.3.1 Conditional Evaluation

Conditional evaluation will check the value of a Boolean expression and then evaluate the appropriate block of code. One of the most common ways to do this is with an if statement.

```julia
if x < y
    # run this if x < y
elseif x > y
    # run this if x > y
else
    # run this if x == y
end
```

We can also use the ternary operator with its question mark and colon syntax. It checks the Boolean expression before the question mark. If the expression evaluates to true, then it returns what comes before the colon; otherwise it returns what comes after the colon.

```julia
julia> f(x) = x > 0 ? x : 0;
julia> f(-10)
0
julia> f(10)
10
```
G.3.2 Loops

A loop allows for repeated evaluation of expressions. One type of loop is the while loop. It repeatedly evaluates a block of expressions until the specified condition after the while keyword is met. The following example sums the values in the array \( x \).

\[
\begin{align*}
X &= [1, 2, 3, 4, 6, 8, 11, 13, 16, 18] \\
s &= 0 \\
while \! \! isempty(X) \\
    &\quad s += pop!(X) \\
end
\end{align*}
\]

Another type of loop is the for loop. It uses the for keyword. The following example will also sum over the values in the array \( x \) but will not modify \( x \).

\[
\begin{align*}
X &= [1, 2, 3, 4, 6, 8, 11, 13, 16, 18] \\
s &= 0 \\
for y in X \\
    &\quad s += y \\
end
\end{align*}
\]

The in can be substituted with = or \( \in \). The following code block is equivalent.

\[
\begin{align*}
X &= [1, 2, 3, 4, 6, 8, 11, 13, 16, 18] \\
s &= 0 \\
for i = 1:length(X) \\
    &\quad s += X[i] \\
end
\end{align*}
\]

G.3.3 Iterators

We can iterate over collections in contexts such as for loops and array comprehensions. To demonstrate various iterators, we will use the collect function, which returns an array of all items generated by an iterator:

\[
\begin{align*}
\texttt{julia> X} &= ["feed", "sing", "ignore"] \\
\texttt{julia> collect(enumerate(X))]} &\quad \text{# return the count and the element} \\
&\text{3-element Vector\{Tuple\{Int64, String\}\}:} \\
&\quad (1, "feed") \\
&\quad (2, "sing") \\
&\quad (3, "ignore") \\
\texttt{julia> collect(eachindex(X))]} &\quad \text{# equivalent to 1:length(X)} \\
&\text{3-element Vector\{Int64\}:}
\end{align*}
\]
G.4 Packages

A package is a collection of Julia code and possibly other external libraries that can be imported to provide additional functionality. This section briefly reviews a few of the key packages that we build upon. To add a registered package like Distributions.jl, we can run:

```julia
using Pkg
Pkg.add("Distributions")
```

To update packages, we use:
Pkg.update()

To use a package, we use the keyword using:

using Distributions

G.4.1 LightGraphs.jl

We use the LightGraphs.jl package (version 1.3) to represent graphs and perform operations on them:

julia> using LightGraphs
julia> G = SimpleDiGraph(3);  # create a directed graph with three nodes
julia> add_edge!(G, 1, 3);    # add edge from node 1 to 3
julia> add_edge!(G, 1, 2);    # add edge from node 1 to 2
julia> rem_edge!(G, 1, 3);   # remove edge from node 1 to 3
julia> add_edge!(G, 2, 3);   # add edge from node 2 to 3
julia> typeof(G)             # type of the graph
LightGraphs.SimpleGraphs.SimpleDiGraph{Int64}

julia> nv(G)                  # number of nodes (also called vertices)
3
julia> outneighbors(G, 1)    # list of outgoing neighbors for node 1
1-element Vector{Int64}:
   2
julia> inneighbors(G, 1)     # list of incoming neighbors for node 1
Int64[]

G.4.2 Distributions.jl

We use the Distributions.jl package (version 0.24) to represent, fit, and sample from probability distributions:

julia> using Distributions
julia> μ, σ = 5.0, 2.5;
julia> dist = Normal(μ, σ)   # create a normal distribution
Distributions.Normal{Float64}(μ=5.0, σ=2.5)
julia> rand(dist)            # sample from the distribution
7.680840742730046
julia> data = rand(dist, 3) # generate three samples
3-element Vector{Float64}:
   2.33566342700474
   5.32781654818515
   6.886978963547712
julia> data = rand(dist, 1000); # generate many samples
```julia
Distributions.fit(Normal, data) # fit a normal distribution to the samples
Distributions.Normal{Float64}(μ=4.948693961824282, σ=2.4522197524266898)

μ = [1.0, 2.0];
Σ = [1.0 0.5; 0.5 2.0];

dist = MvNormal(μ, Σ) # create a multivariate normal distribution

dist = Dirichlet(ones(3)) # create a Dirichlet distribution Dir(1,1,1)

rand(dist, 3) # generate three samples

rand(dist) # sample from the distribution
```

**G.4.3 JuMP.jl**

We use the JuMP.jl package (version 0.21) to specify optimization problems that we can then solve using a variety of different solvers, such as those included in GLPK.jl and Ipopt.jl:

```julia
using JuMP
using GLPK

model = Model(GLPK.Optimizer) # create model and use GLPK as solver

@variable(model, x[1:3]) # define variables x[1], x[2], and x[3]

@objective(model, Max, sum(x) - x[2]) # define maximization objective
```

2021-07-20 17:04:22-07:00, revision 2babf1f, comments to bugs@algorithmsbook.com
julia> @constraint(model, x[1] + x[2] ≤ 3)  # add constraint
julia> @constraint(model, x[2] + x[3] ≤ 2)  # add another constraint
julia> @constraint(model, x[2] ≥ 0)  # add another constraint
x[2] ≥ 0.0
julia> optimize!(model)  # solve
julia> value.(x)  # extract optimal values for elements in x
3-element Vector{Float64}:
  3.0
  0.0
  2.0

G.5 Convenience Functions

There are a few functions that allow us to more compactly specify the algorithms in the body of this book. Julia 1.7 will support a two-argument version of `findmax`, where we can pass in a function and a collection. It returns the maximum of the function when evaluated on the elements of the collection along with the first maximizing element. The `argmax` function is similar, but it only returns the first maximizing element. To support this in Julia 1.6, we manually extend these functions.

```julia
function Base.findmax(f::Function, xs)
    f_max = -Inf
    x_max = first(xs)
    for x in xs
        v = f(x)
        if v > f_max
            f_max, x_max = v, x
        end
    end
    return f_max, x_max
end

Base.argmax(f::Function, xs) = findmax(f, xs)[2]
```

```julia
julia> findmax(x->x^2, [0, -10, 3])
(100, -10)
julia> argmax(abs, [0, -10, 3])
-10
```
The following functions are useful when working with dictionaries and named tuples:

```julia
Base.Dict{Symbol,V}(a::NamedTuple) where V =
    Dict{Symbol,V}(n⇒v for (n,v) in zip(keys(a), values(a)))
Base.convert(::Type{Dict{Symbol,V}}, a::NamedTuple) where V =
    Dict{Symbol,V}(a)
Base.isequal(a::Dict{Symbol,<:Any}, nt::NamedTuple) =
    length(a) == length(nt) &&
    all(a[n] == v for (n,v) in zip(keys(nt), values(nt)))
```

```julia
julia> a = Dict{Symbol,Integer}((a=1, b=2, c=3))
    Dict{Symbol, Integer} with 3 entries:
    :a => 1
    :b => 2
    :c => 3
julia> isequal(a, (a=1, b=2, c=3))
    true
julia> isequal(a, (a=1, c=3, b=2))
    true
julia> Dict{Dict{Symbol, Integer},Float64}((a=1, b=1)↦0.2, (a=1, b=2)↦0.8)
    Dict{Dict{Symbol, Integer}, Float64} with 2 entries:
    Dict(:a=>1, :b=>1) => 0.2
    Dict(:a=>1, :b=>2) => 0.8
```

We define `SetCategorical` to represent distributions over discrete sets.

```julia
struct SetCategorical[S]
    elements::Vector{S} # Set elements (could be repeated)
    distr::Categorical   # Categorical distribution over set elements

    function SetCategorical(elements::AbstractVector{S}) where S
        weights = ones(length(elements))
        return new[S](elements, Categorical(normalize(weights, 1)))
    end

    function SetCategorical(elements::AbstractVector{S}, weights::AbstractVector{Float64}) where S
        ℓ₁ = norm(weights, 1)
        if ℓ₁ < 1e-6 || isnan(ℓ₁)
            return SetCategorical(elements)
        end
        distr = Categorical(normalize(weights, 1))
        return new[S](elements, distr)
    end
end
```
Distributions.rand(D::SetCategorical) = D.elements[rand(D.distr)]
Distributions.rand(D::SetCategorical, n::Int) = D.elements[rand(D.distr, n)]
function Distributions.pdf(D::SetCategorical, x)
    sum(e == x ? w : 0.0 for (e,w) in zip(D.elements, D.distr.p))
end

julia> D = SetCategorical(["up", "down", "left", "right"],[0.4, 0.2, 0.3, 0.1]);
julia> rand(D)
"down"
julia> rand(D, 5)
5-element Vector{String}:
  "right"
  "down"
  "up"
  "left"
  "down"

julia> pdf(D, "up")
0.3999999999999999
